

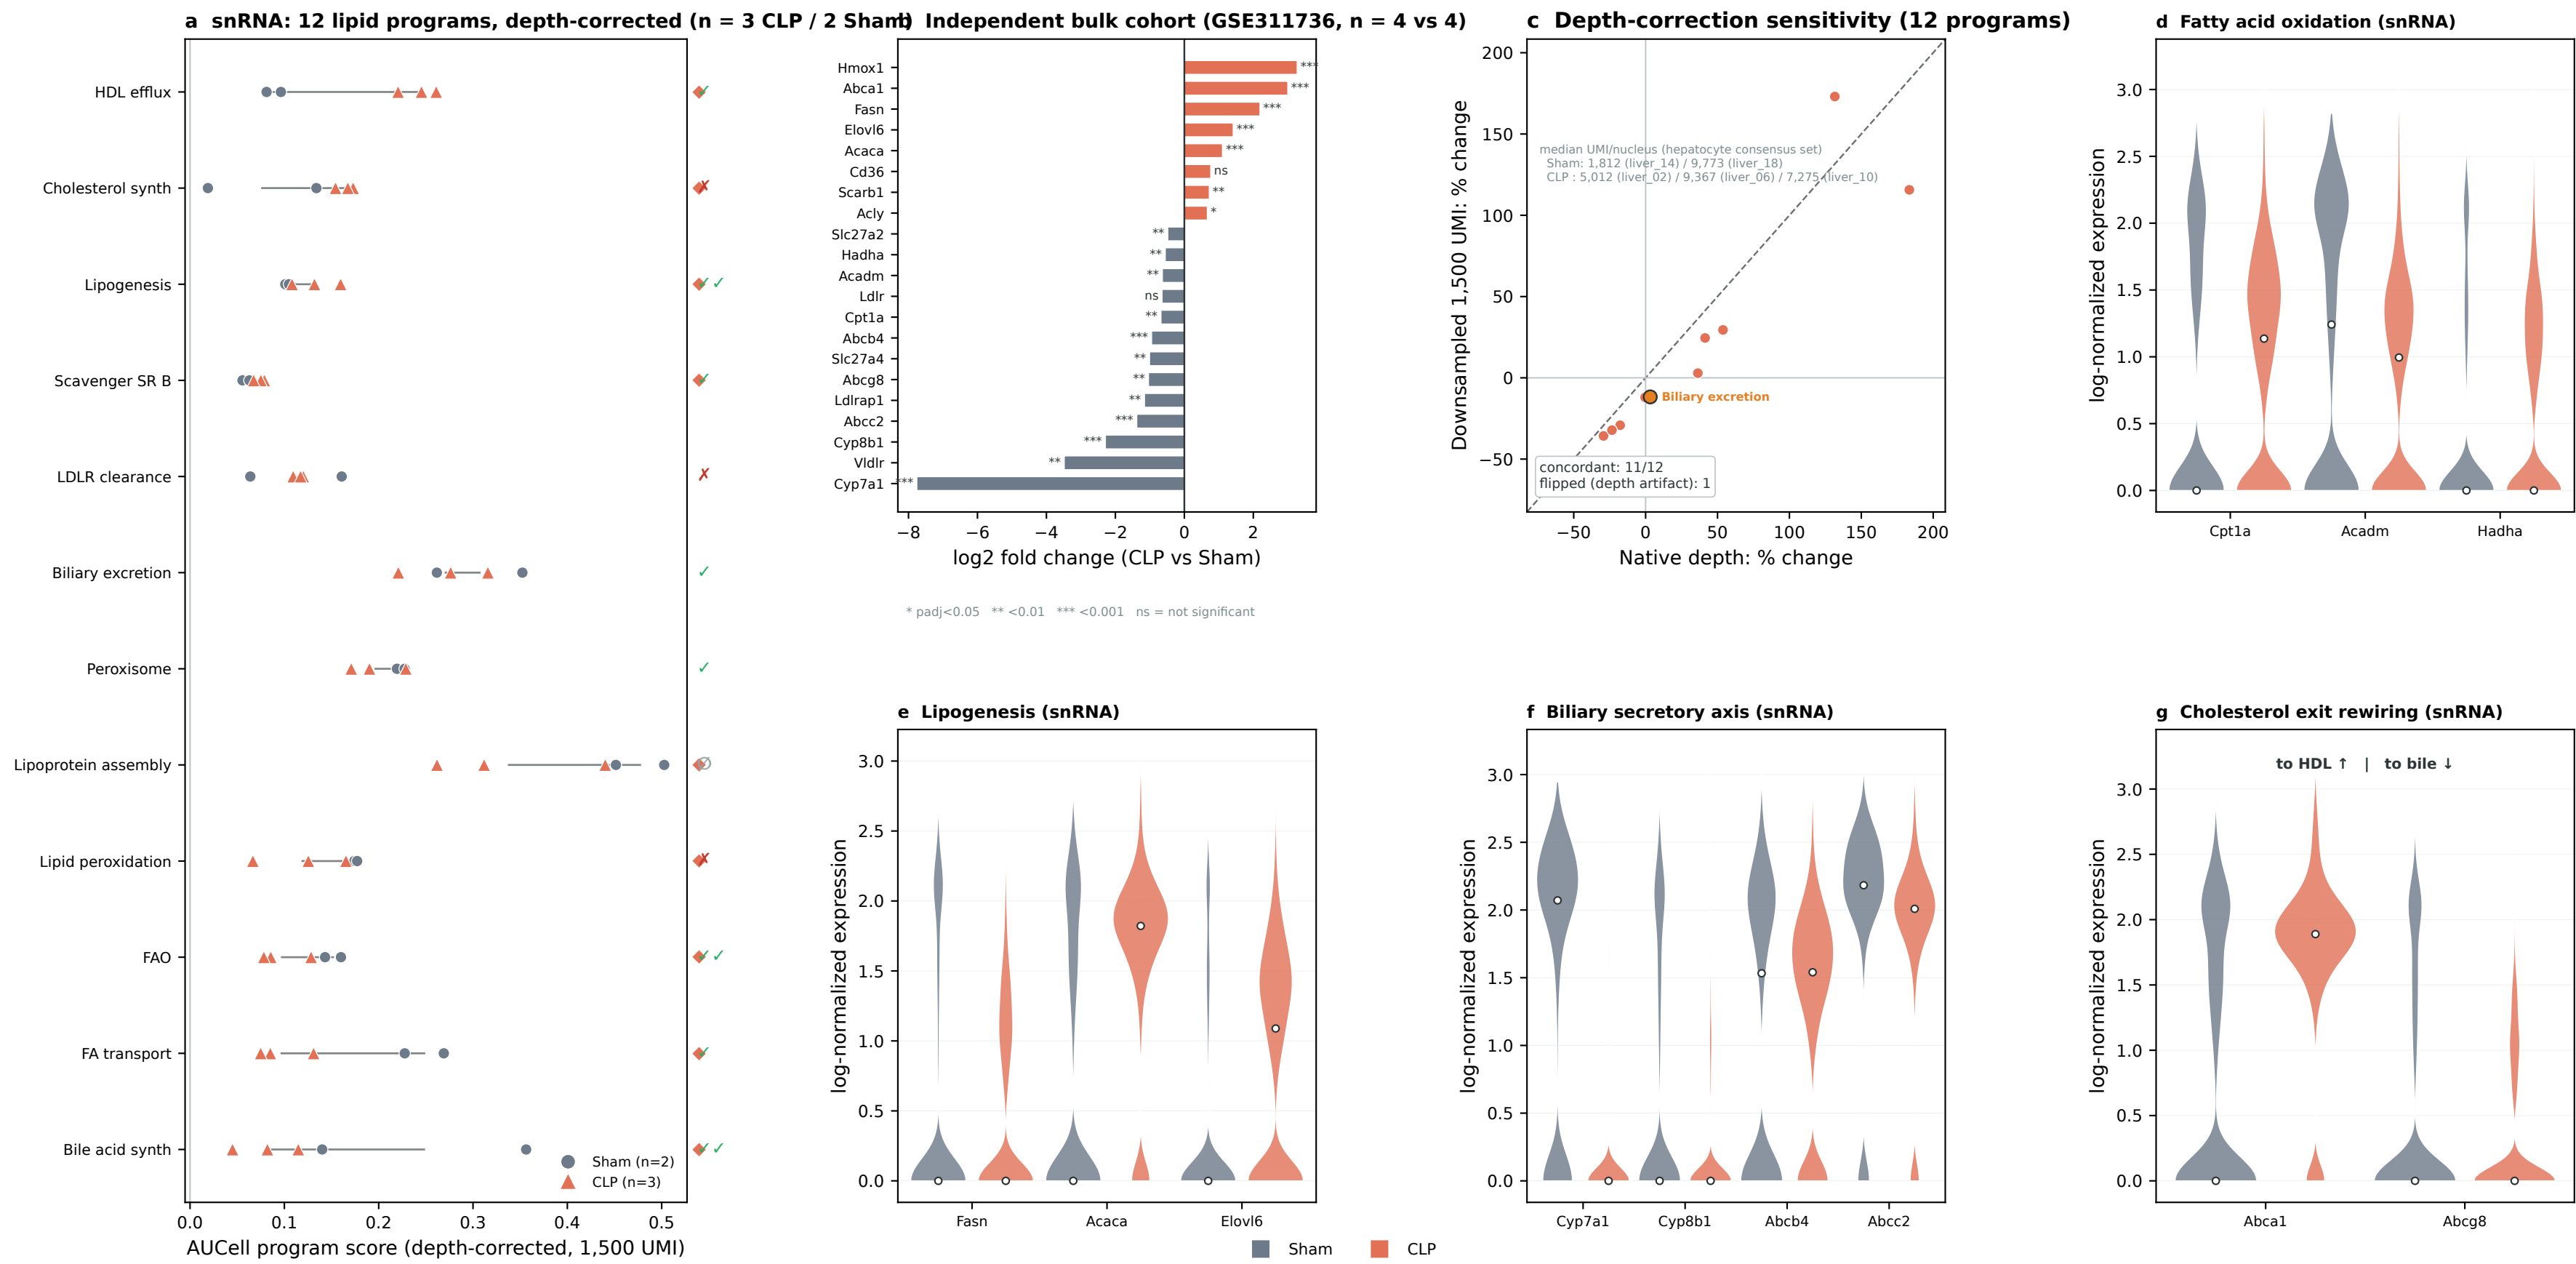

Figure 3 Hepatocyte lipid reprogramming in sepsis: exogenous import and biliary excretion shut down, while lipogenesis and ABCA1-mediated HDL efflux are induced

◆ = complete sample separation: all three CLP samples fall outside the sham range. With n = 3 vs 2 the smallest attainable two-sided permutation p is 0.100, so ◆ is descriptive only and does NOT denote significance. Right column = depth-corrected snRNA vs independent bulk: ✓✓ concordant & gene-set p<0.05 ✓ concordant ✗ direction discordant ∅ no gene with padj<0.05 in bulk (null, not discordant)
